     The matrix-forming material of the title asbestos-free fiber-reinforced
     articles with d. ≥1000 kg/m3 comprises (A) a coarse material with
     average particle size 12-35 \mu, preferably 18-25 \mu with size distribution
     having only 1 maximum and containing a <u>hydraulic binder</u> and possible a SiO2- or silicate-containing, preferably pozzolanically active additive 40-90, preferably 45-85; (B) a fine inorg., preferably SiO2- or
     silicate-containing, especially pozzolanically active additive with average particle
     size 1-10 \mu, preferably 3-7 \mu with particle size distribution having
     only 1 maximum 5-45, preferably 10-40, in particular 10-35; (C) an ultrafine,
     preferably pozzolanically active additive with average particle size 0.02-1
     \mu, preferably <0.5 \mu 3-25; and (D) other additives 0-30 dry weight%.
     Green, shaped articles are formed by dewatering an aqueous slurry of fibers
     and the matrix-forming material containing excess water over the amount
     necessary for curing the hydraulic binder in the
     matrix and containing cellulose fibers 3-20, preferably 5-20, in particular
     7-15 dry weight% and the green articles are cured. Compns. suitable for
     dewatering on Hatschek and Magnani machines are claimed. Sheets prepared
     from a thick slurry of bleached cellulose
     fibers (length 1.0 mm, diameter .apprx.15 µ) 9, unbleached
     cellulose fibers (length <4 mm, diameter .apprx.35 μ) 3, low-alkali
     sulfate-resistant portland cement (90% <44 \mu and 10% <3.2
     \mu) 47, ground fly ash (90% <30 \mu, 50% <5.4 \mu, and 10% <1.0 \mu)
     21, and SiO2 dust (average particle diameter 0.1 \mu) 20% had filtration time
     103 s and with autoclaving temperature 160° had modulus of rupture 20.3
     MPa and d. 1399 \text{ kg/m3} \text{ vs. } 41 \text{ s, } 15.6 \text{ MPa, and } 1284 \text{ kg/m3} \text{ with unground fly}
     ash (90% <44 \mu, 50% <14 \mu, and 10% <4.4 \mu) as fine component
     instead of ground fly ash.

#### Description

10

The present invention relates to a process for the manufacture of asbestos-free fibre-reinforced shaped articles having a density of at least 1000 kg/m<sup>3</sup> with a matrix of a cured inorganic binder, in which green shaped articles are formed by dewatering an aqueous sturry of fibres and a matrix forming material comprising particles of an inorganic hydraulic binder, a particulate inorganic additive and possibly other additives containing an excess of water in relation to the amount necessary to secure curing of the hydraulic binder, and containing, on a dry weight basis, 3-20%, preferably 5-20%, in particular 7-15%, cellulose fibres, after which the green shaped articles are cured.

Various processes of this kind are known in connection with the above procedure. Hereby the curing of the green chaped articles, which may be pressed or unpressed, may take place at atmospheric pressure, e.g. at temperatures between about 20 and 100°C, or by autoclaving, i.e. heat treatment in the presence of caturated steam at super-atmospheric pressure.

"Pressed shaped articles" are products, during the manufacture of which the green shaped articles are compressed in an additional compression step, typically at a compression pressure of approx. 10 MPs. "Unpressed shaped articles" are shaped articles which have not been subjected to such an additional compression step.

The known autoclaved and unautoclaved products have typically a modulus of rupture, MOR, of at least 8 MPa, e.g. 8-16 MPa and are well-autied as building materials, e.g such as flat or corrugated sheets and panels used for roofing and interior and exterior cladding of buildings.

Numerous processes of this kind are known in connection with the manufacture of unautoclaved pro-

For example US patent specification No. 4 281 754 describes the manufacture of building materials reinforced with special polyolefine-tibres and possibly calfuloss fibres, by which, if desired, an inorganic fine grained additive may be added, i.e. to provide improved plasticity and fibre dispersion during the manufacture of the green sheets. Typical MOR values for such unautoclaved polyolefine-fibre-reinforced sheets are about 6 MPa.

Danish patent specification No. 4926/78 describes an improved solution to the problem of providing fine fibre dispersion, which is obtained by intensive mechanical treatment of the fibre-containing shurry prior to dewatering same. It also describes the use of a fine filler, such as ultra fine silica dust, hereinafter "UFS". having a specific surface area of 5-200 m²/g and an average particle diameter less than about 0.5 µm dosed in an amount of as much as 10%, typically 2-5%, in particular 3.5%, in connection with the manufacture of unautoclaved fibre-reinforced sheets with a typical MOR of about 10 MPa. Here and in the following all percentages are calculated by weight unless otherwise indicated.

It was later discovered that the said intensive treatment could be evoided, if, during the manufacture of the initially prepared aqueous fibre clurry, colloidal hydrophilib particles are used as dispersion agent, e.g. special colloidal silica-and/or clay particles, such as Aerosil 200 and Ludox HS40, in amounts of approx. 2%. Typical cellulose fiber-dosages are 2-3%, typical binding agents are Portiand cement and pozzolanic caments, e.g. containing up to 12% of the above UFS as pozzolan. This technique is described in EP patent specification No. 47 168, but exclusively in connection with the manufacture of unautoclaved sheet products. Hereby are obtained products with considerably improved strength properties. e.g. typical MOR values of 12-18 MPa at densities of about 1600 kg/m³.

Addition of plastifying agents in the form of colloidal silica- and/or day particles, such as Cabosil or bentonits, in amounts of 5-10% when manufacturing both unautodaved and autodaved sheets with high density and containing at least 5% cellulose fibres is known from GB patent specification No. 2 045 308. A typical redpe for flat sheets is e.g. 84.5% Portland cement, 10.9% cotton fibres, 0.5% nylon fibres and 6.0% plastifying agent, such as celloidal eilica, thus producing products with MOR values of about 19.5 MPa at a density of about 1450 kg/m².

GB patent specification No. 2 048 330 and EP patent specification No. 68 742 e.g. describe the use of the above UFS as pozzolan in the manufacture of unautoclaved sheets. The latter specification concerns the manufacture of e.g. flat or corrugated, preferably pressed, cellulose fibre-reinforced sheets, typically having the following composition: 8% ootton fibres, 87% Portland coment and 25% UFS. After curing for 24 h at 80°C and for 2 weeks at room temperature pressed products are obtained having MOR values of about 18 MPa at a darsity of about 1500 kg/m³.

Finally numerous variants of the process described in the introduction are known in connection with the manufacture of autoclaved products.

the manufacture of autocaved products.

It is a characteristic common feature of these methods that the equeous slurry contains three main components: A fibre component, a time component and an acid silica component, the acidity of the latter usually

only manifesting itself under the reaction conditions prevailing during the autoclaving process. Additionally various additives can be used, i.e. plastifying agents in the form of colicidal silica- and/or clay particles, such as Cabosil, Ludox and bentonite. Known lime components include Portland cement, hydrated lime and mixtures thereof. Known acid allica components reacting during the autoclaving with the lime component under formation of calcium ellicate hydrates include ground quartz, allica sand, distornite and/or fly ash having a fineness corresponding to that of Portland cement.

A significant difference between autoclaved and unautoclaved products resides in the different chemical and crystalline nature of the cured binders. Whereas the unautoclaved, cured binders mainly consist of amorphous calcium silicate hydrates with fairly varying stoichiometry and containing free lime, the autoclaved products mainly consist of semi-, mainly extremely fine-crystalline tobermorite-like structures with less varying stoichiometry, containing practically no free lime. The chamical and morphological structure of the varying stoichiometry, containing practically no free lime. The chamical and morphological structure of the start-autoclaved matrixes is, however, a complex function of a number of factors, including the nature of the starting materials and the reaction conditions before and during the autoclaving. Due to i.e.the more crystalline nature of the matrixes the autoclaved products often exhibit improved weather resistance, reduced molature movements and reduced molature permeability compared with the corresponding properties of the unautoclaved products.

A typical example of a fibre-reinforced autoclaved product is described in US patent specification No. 3 501 323, which mentions a typical mixture of 15% asbestos fibres, 51% Portland cement and 34% ground sand (as silice). A free flowing aqueous slurry is prepared from this mixture, whereafter green sheats are prepared by dewatering said slurry. These sheets are pressed and autoclaved, typically at 170°C for 8 hours.

Similar processes using hydrated lime, Portland cament or mixtures thereof, ground quartz, silica sand, diatomite or fly ash so silica, preferably having a specific surface area within the range 3000-5000 cm<sup>2</sup>/g, and fibres of asbestos, effica, glass, cellulose and/or organic polymers, are also mentioned in US patent specification No. 3 501 323.

Another process of the same kind for the production of asbestos-free products, using e.g. 12% cellulose fibres, 15% Portland cement, 31.6% hydrated lime, 29.2% ground quartz end 12% mice is known from US specification No. 4 101 335. This product has a typical density of 750 kg/m² and a MOR of 13.5 MPa.

Autoclaved products of this kind are also described on page 5 of Danish patent specification No. 3879/80, e.g. containing 3% osliulose fibres, 9% hydrated lime, 40% fly asb, approx. 30% Portland cement, 12% Wellastonite crystals and 6% dispersion egent in the form of a clay slurry. This product has a density of approx 1300 kg/m³ and a MOR of about 7 MPa.

30

50

53

Autoclaved cellulose fibre-reinforced products are further described in the following specifications:

GB patent specification No. 1 421 556 describing the manufacture of autoclaved products, e.g. on the basis of raw mixtures with the recipe 38.2% Portland coment, 39.1% diatomite, 5% cellulose fibres, 12.2% glass fibres and 7.5% perilip having a MOR of 4.7 MPa at a density of 640 kg/m $^3$ ;

US patent specification No. 4 040 851 describing the manufacture of suroclaved products, e.g. on the besis of raw mixtures with the recipe 50.1% Portland cement, 18.6% disternite, 6.2% cellulose fibres and various additives having a MOR of about 9 MPs at a density of 930 kg/m², and a corresponding product with ground quartz instead of distornite having a MOR of about 21 MPs at a density of 1600 kg/m³; and

US patent specification No. 4 132 555 describing the manufacture of autoclaved products, e.g. on the basis of raw modures with the recipe 10% Portland cement, 42% hydrated lime, 38% ground quartz and 10% cellulose fibres having a MOR of 10.6 MPa at a density of 755 kg/m³.

As previously mentioned, the use of plastifying agents in the form of colloidal silica- and/or clay particles, such as Cabosil, Gasil, Neosyl and bentonite, is also known in connection with the manufacture of autoclaved products, e.g. from GB patent specification No. 2 045 308, which e.g. mentions the manufacture of autoclaved products on the basis of raw mbdures with the recipe 41% Portiand cement, 44% ground quartz, 4% cotton callulose fibres, 2% other fibres and 9% bentonite having a MOR of 18.5 MPa at a density of 1400 kg/m³, and with the racipe 46% hydrated lime, 41.5% ground quartz, 4% cellulose fibres, 5.5% other fibres and 9% bentonite having a MOR of 16.5 MPa at a density of 1350 kg/m³.

Another process of the same kind using 40-80% cement, 30-40% ground quartz and 5-15% cellulose fibres and possibly plastifying agents of the same kind, e.g. colloidal effice, which may partly replace the quartz, e.g. approx. 25% quartz and 10% colloidal effica dispersion agent, is also known from the specification of EP patent specification No. 68 741. Hereby pressed sheets having a density of about 1550 kg/m<sup>3</sup> and MOR values of 16-18 MPa may be produced.

Finally, EP patent specification No. 127 960 describes the manufacture of autoclaved fibre-reinforced shaped articles having a density of at least 600 kg/m³ with a matrix of cured calcium allicate binder by a process, comprising the steps of initially preparing an equature sturry of fibres, containing at least 5% cellulose fibres calculated on the total solid content, silica, lime and/or lime-containing material, such as Port-

land cement, and possibly plastifying agents in the form of colloidal silica- and/or day particles and other additives and containing an excess of water in relation to the amount necessary to secure curing of the calcium silicate binder, subsequently forming green shaped articles by dewatering the slurry, and finally autoclaying the green shaped articles, possibly after pressing and precuring. According to this process the equeous slurry, calculated on a dry weight basis contains

5-30%, preferably 8-20%, in particular 12-16% fibres, preferably at least 8% cellulose fibres, 5-30%, preferably 18-36%, in particular 18-25% silics in the form of ultra fine silics dust with a specific surface area of 5-200 m²/g, and a particular verage diameter less than about 0.5 µm, 20-80%, preferably 30-70%, in particular 45-85% lime and/or time-containing material, such as Portland

cement and 0-40% additives.

The shaped articles formed by this process exhibit particularly high strengths relative to their density. It is however, a characteristic feature of these and the other products mentioned above that there is a significant difference in the densities as well as in the MOR values of unpressed and pressed products, respectively. As a rule, superior strength properties are only obtained when the products are manufactured by processes comprising presseling of the green sheets in an additional compression step, typically at a pressure of about 10 MPs. This is probably due partly to the more compact character of the matrix of the pressed products, which not only per se possess a higher MOR, but also provides improved fibre anchoring compared with the fibre anchoring obtained with the more porous matrix obtained in an unpressed sheet.

However, the necessity of such an additional sheet compression step in the manufacturing of sheets represents a considerable inconvenience, parity for reasons of investment, parity because it complicates the manufacturing process, particularly when corrugated sheets are produced.

Another disadvantage of the known art consists in that the MOR value of water saturated cellulose fibre-reinforced sheets normally amounts to only about 60% of the value for dry sheets. Probably, this reduced strength of wet sheets in relation to dry sheets is due to reduced fibre anchoring in the wet matrix as compared with a dry matrix.

The object of the present invention consists in providing a process of the above kind for the manufacture of products, such as flat or corrugated panels or sheets, e.g. used for roofing, interior and exterior cladding of buildings, and as interior building elements in ships, and pipes, in which the above disadvantages are eliminated and in which the green shaped articles exhibit extremely fine mouldability and plasticity.

It has surprisingly been found that the object can be achieved by a process of the kind described in the introductory part of this specification, characterized in that the matrix forming material comprises, on a dry weight basis.

40-90%, preferably 45-85%, of a coarse material with an average particle size of 35-12 μm, preferably 25-18 μm, preferably with a particle size distribution exhibiting only one maximum, comprising the hydraulic binder and possibly a slice- or elicate-containing, preferably pozzolanic active additive,

5-45%, preferably 10-40%, in particular 10-35%, of a fine inorganic, preferably silica- or silicate-containing, in particular pozzolanic active additive with an average particle size of 10-1 µm, preferably 7-3 µm, preferably with a particle size distribution axhibiting only one maximum,

3-25% of an ultra fine preferably pozzolanic active additive with an average particle size within the range  $1-0.02~\mu m$ , preferably less than  $0.5~\mu m$ , and

0-30% other additives.

The unpressed products formed by the process according to the invention thus exhibit values for density and MOR, which previously could only be obtained for pressed products. Furthermore, the difference between the MOR value in wet and dry state is surprisingly small for products manufactured according to the invention. This advantage is particularly important in connection with the manufacture of pipes.

As in the known set, the matrix forming material comprises an ultra fine additive with a particle size which mainly lies within the range 1 µm to 0.02 µm, and a main fraction comprising hydraulic binder and additive with a particle size which mainly lies within the range 60 µm to 1 µm. According to the known art, the dominating amount of the main fraction (calculated on a weight basis) is in the 50-10 µm-fraction. For as well portland coment, as ordinary unground fly ash and ground quartz the weight ratio between the 60-10-µm-fraction and the 10-1 µm-fraction, hereinafter referred to as the "F-ratio", is thus larger than 1.0, typical values are larger than 1.2.

It is a characteristic feature of the matrix forming material according to the invention that its F-ratio is smaller than the F-ratio according to the known art, due to the addition of the fine additive having an average particle size of 10-1 µm, and an F-ratio less than 1.0.

This is believed to result in a more close and compact packing of the matrix-material in the dewatered product, accounting for the fact that the present products exhibit not only higher density but also higher MOR

values, probably as a result of improved inherent matrix strength and improved fibre anchoring in the matrix. Furthermore, the green shaped articles manufactured by the process according to the invention exhibit excellent plasticity, handabiliby and shapability which are particularly advantageous in connection with the manufacture of corrugated sheets and hand-moulded goods.

By the process according to the invention it is possible to manufacture unpressed flat sheets with typical dry MOR values, vtz. BT-max. dry (defined below), of 19-35 MPa at densities of 1200-1450 kg/m². Typically, the wet MOR values are at the most 10% smaller than the corresponding dry values.

The process according to the invention may be carried out on both Hatschek and Magnani Machines in connection with preparation of in particular unpressed but if desired also pressed sheets, and on Mazza and Magnani Machines in connection with preparation of pipes.

The curing of the green shaped articles may take place at stracepheric pressure, e.g. at temperatures between about 20 and 100 °C, or by autoclaving.

When manufacturing unsutoclaved materials the total amount of fine and ultra fine material preferably constitutes less than 35%, calculated on the the total solld content in the slurry, and the coarse material preferably consists exclusively of the hydraulic binder.

According to a preferred embodiment of the process according to the invention, the dewatering step is carried cut on a Hatschek Machine and the green shaped articles are cured by autoclaving. In this case the matrix forming material may comprise, on a dry weight basis,

40-75%, preferably 40-55%, in particular 45-50% of the coarse material,

10-45%, preferably 15-40%, in particular 20-30% of the fine additive,

3-25%, preferably 10-25%, in particular 14-22% of the ultra fine additive, and 0-30% other additives.

According to another preferred embodiment of the process according to the invention, the dewatering step is carried out on a Magnani Machine and the green shaped anticles are cured by autoclaving. In this case the matrix forming material may comprise, on a dry weight basis,

40-75%, preferably 40-60%, in particular 45-55% of the coarse material,

10-45%, preferably 16-40, in particular 25-35% of the fine additive,

3-25%, preferably 8-20%, in particular 5-15% of the ultra fine additive, and

0-30% other additives. According to another preferred embodiment of the process according to the invention, the dewatering step is carried out on a Hatachak Machine or a Magnani Machine and the green shaped articles are cured at atmospheric pressure. In this case the matrix forming material may comprise, on a dry weight basis, 50-90%, preferably 60-90%, in particular 65-85% of the coarse material,

5-35%, preferably 10-30%, in particular 10-20% of the fine additive,

3-25%, preferably 5-20%, in particular 5-15% of the ultra fine additive, and 0-30% other additives.

According to preferred embodiments of the process according to the invention the 50-1-um-fraction of the coarse material constitutes at least 80% by weight of said material, and the weight ratio of the 50-10-jum-fraction to the 10-1-jum-fraction of this material is larger than 1.0, preferably

the 50-1-um-fraction of the fine additive constitutes at least 80% by weight of said material, and the weight larger than 1.2, ratio of the 50-10-jun-fraction to the 10-1-jun-fraction of this material is less than 1.0, preferably less than

at least 80% by weight of the ultra fine additive has a particle size within the range 0.5-0.02 µm.

The hydraulic binder is preferably Portland cament, e.g. of the type I-V, eccording to ASTM standard C 150, preferably having a Blaine-value lower than 2500 cm<sup>2</sup>/g.

The coarse material may comprise more than one type of coarse material with an average particle size of 95-12 p.m., e.g., a mixture of Portland coment and stilica- or stilicate-containing, preferably pozzolanic active additives, such as unground fly ash and/or possibly ground quartz, with a weight ratio Portland coment/additive larger than 1, preferably larger than 1.2.

According to a professed embodiment of the process according to the invention the fine additive is ground fly ash, possibly ground, possibly calcined moler, ground quartz, kleselgur, rice husk ash, calcium carbonate or Wollastonite.

The ultra fine additive is preferably fine filter dust from electrothermal production of silicon or ferrosilicon with a specific surface area of about 25 m $^2$ /g and an average particle diameter of about 0.1  $\mu m$ .

Preferred fibres are ; synthetic inorganic fibres, such as mineral wool, glass, carbon and steel fibres ; synthetic organic fibres, such as polyaster, polyvinyl, polyvinylalcohol, polyethylene, polypropylene, polyacrytonibile and polyacrytamide fibree; and/or natural organic fibree, such as cellulose fibree.

As mentioned above, the squeous slurry contains 3-20 weight-%, preferably 5-20 weight-%, in particular 7-15 weight-%, calculated on a dry weight basis, cellulose fibres. Preferred cellulose fibres are selected from : wood fibres of e.g. birch, eucalyptus, pine and spruce; seed and fruit heir fibres of e.g. coir and cotton; and leaf and/or bast fibres of e.g. sisal, abaca, flex, hemp and jute.

The fibres serve partly to reinforce the cured product, partly as filtration and retention alde at the dewa-

tering atop. Particularly satisfactory filtration and retention are obtained when at least a part of the cellulose fibres is refined to a degree of fineness of 20-80° Schopper Riegler, and/or when the fibres include highly fibrillated polyethylene or polypropylene fibres.

According to a preferred embodiment the fibres are exclusively cellulose fibres.

As mentioned above the matrix forming material may comprise 0-30% other additives. These may be selected from : fillers, such as mica, vermiculits, peritis and expanded day ; colouring agents, water sealing aganta, setting and hardening accelerators, such as calcium chloride and aluminium sulphate, flocculants or dispursants, tiltering alds, such as scicular Wollastonite crystals, and organic or inorganic plastifying and fibre dispersion agents, such as hydrophilic inorganic particles, i.a. colloidal silica particles and refined or unrefined colleided casy particles with a dominating particle fraction less than 0.02  $\mu m$ .

The autoclaving is preferably performed at temperatures between 100 and 240°C, in particular within

the interval 130-190°C. The equeous clurry can be prepared in a manner known per se by pulping and stirring the fibres in water and subsequently admitting the remaining materials, possibly adding more water to reach a suitable water/solid ratio.

When using ultra fine stilles as ultra fine additive it has, however, been found particularly advantageous initially to disperse the ultra-line silica in water having a pH-value exceeding 8, subsequently stiming the fibres in this aqueous silica dispersion and finally admixing the remaining materials and, if necessary, additional water. Hereby is ensured a particularly homogeneous aluny of the fibres with a reduced tendency to lump formation, presumably because the ultra fine silics dust in a basic environment will coat the surface of the individual cellulose fibres, providing an increased dispersibility of the cellulose fibres.

The preparation of the green shaped articles by dewatering the slurry takes place in a manner known per as, e.g. using the Hatschek, Magnani, Mazza, Head Box, flow on, injection or Foundainier method.

The green chaped articles can, for example, be chaped as beams, blocks, pipes and flat or corrugated sheets and panels which, if desired, can be subjected to compression in an additional compression step, typically at a pressure of 1-10 MPa. When manufacturing autoclaved products the green shaped articles are preferably subjected to a precuring step, typically at 20-100°C for 6-24 hours and a relative humidity of 80-100%, before the autoclaving step.

The invention is further likestrated in the Examples.

The materials used in the examples were as follows:

#### Fibres:

EO calidoso:

Bleached ositulose fibres (Eucalyptus grandis and Eucalyptus urophylla) having a dewatering resistance of about 20° SR, length; about 1.0 mm, diameter; about 15 µm.

Sandamo K:

Unbleached cellulose fibres (Pinus) (Kraft cellulose),

length: less than 4 mm,

diameter: about 35 µm having a dewatering resistance of about 14° 8R.

Sandame K, xº SR:

Sandame K refined to a dewatering resistance of x° SR; x = 20, 21, 29.

Store 32:

Bleached cellulose fibres (Pinus) (Kraft cellulose),

length: less than 4 mm,

diamater: about 85 µm having a dewatering resistance of about 14° SR.

Stora 32, 40° SR:

Stora 32 refined to a dewatering resistance of 40° SR.

# Hydraulic binder:

A sulphate-resistant Portland cement having a low alloat content (mex. 0.80%) (type V), specific surface (Blaine): 2300 cm²/g, C<sub>2</sub>A-content: about 1.5%, F-value: about 2.2, average particle size: about 20 μm.

An ordinary Portland coment (type III), specific surface (Biaine): 4880 cm²/g, C,A-content: about 10%, value : about 1.4, average particle size : about 13 μπ.

10

### Additives:

Silica sand containing at least 90% SiO<sub>2</sub>, specific surface (Biaine) : about 4500 cm<sup>2</sup>/g, F-value : about 2.6, average particle size : about 20 µm.

Fly ash from power plant, specific surface (Blaine) : about 3500 cm2/g, F-value : about 1.5, average particle aiza : about 14 µm.

20

#### Fine additive:

Ground fly ash 100, 300, 600, J and G, vide example 1 and table i.

### Ultra fine additive :

Ultra fine allica dust from electrothermal production of metallic silicon or ferrosilicon, 810, content: 60-100%, specific surface (BET) : about 25 m²/g, average particle diameter : about 0.1 μm.

Fibre reinforced sheets were prepared in the laboratory at bench scale and on Hatschek and Magnani Machines at full industrial scale.

# Bench scale experiments:

# Production Procedure:

# Pulp preparation:

A saturated solution (20°C) of Ca(OH)<sub>2</sub> and CaSO<sub>4</sub>, 2H<sub>2</sub>O in delonked water was prepared. A portion of this solution together with the desired amount of ultra fine allica were introduced into a British Pulp Evaluation Apparatus, and the silica was dispersed at 3000 r.p.m for 3 min. Then the fibres were added to the dispersion, and the mixture was pulped at 3000 r.p.m. for 15 min.

# Slurry preparation:

The resulting fibre pulp along with an additional portion of the above saturated solution were transferred to the vessel of a Dial mixer, and the skury was prepared by adding the remaining components of the matrix forming material and optional additives in an amount corresponding to a weight ratio water to total solid material equal to 10 in thin sturry experiments and 3 in thick every experiments. The resulting mixture was stirred at 1000 r.p.m. for 8 min.

# Preparation of green sheets.

A portion of the elumy corresponding to 109 g solid material was dewatered in a filtration apparatus, suction pressure 200 mm Hg. The resulting filter cakes were pressed to green sheets in a Johns-Manville sheet forming press at a compression pressure of 1.5 MPa. The density of the green sheets corresponds to about the density of the unpressed sheets prepared on an industrial scale.

### Preparation of cured sheets:

# Procedure 1 (autoclaving):

The green sheets were cured in the following way: The green sheets were placed on a glass plate and kept in a humidity box for 24 hours, relative humidity : about 95%, temperature 25°C. The sheets were then sunoctaved with a pressurtzing period of 2.6 hours, a full pressure period of 16 hours, and a depressurtzing parlod of 2.5 hours.

# Procedure 2 (ordinary curing):

The green sheets were cured in the following way : The green sheets were placed on a glass plate and kept in a humidity box for 24 hours, relative humidity : about 95%, temperature 25°C. Thereafter the sheets were submerged in water and cured at 20-25°C for 20 days.

# Procedure 3 (accelerated curing):

The green sheets were cured in the following way : The green sheets were placed on a glass plate and kept in a humidity box for 24 hours, relative humidity : about 85%, temperature 25°C. Thereafter the sheets were submarged in water and cured at 20-25°C for 6 days, whereafter the sheets were cured under water for another 14 days at about 60°C.

The physical properties of the slurry and the cured sheets were measured as described below :

#### Testing Procedure:

### Filtration time:

A portion of sturry corresponding to 109 g of solid material was dewatered in a filtration apparatus at a suction pressure equal to 200 mm Hig. A sudden drop in suction pressure indicates the end of the filtration period. The filtration time is defined as the period of time from start of suction to pressure drop.

#### BT-max dry and wet:

The cured sheets were subjected to bending tests in which the curvature of the specimens was determined as a function of the load. A ZWICK 1454 testing machine with 4-point load with a support distance of 190 mm and a 35 mm arm of momentum was used. Force/deformation curves were registered, BT-max designates the bending stress at maximum load, also referred to above as "MOR" (modulus of rupture). "wet" designates that measurements were made on watersoaked sheets which had been submerged in water for 48 hours, and "dry" designates that measurements were made on sheets which had been dried at 110°C for 48 hours.

### Example 1.

# Preparation of ground fly ash.

Ground fly ash was ground to an increasing degree of fineness in a rotating laboratory mill with grinding

Fly sah with three degrees of finaness were produced, designated 100, 300 and 500, the respective specific power consumption being 100, 300 and 500 kWivt.

Two additional types of ground fly ash were produced, designated J and G.

The grain size distribution of these five products, of the unground fly ash, of the cement and ground  $81O_2$  used in the following examples was determined by a sedigraph.

Grain size analysis and F- values for these materials are shown in table i.

Ø

### Example 2.

Comparison between sheets prepared according to the invention and sheets prepared according to the known art (autoclaved products).

Five series of experiments were performed with production of sheets according to the Production Pro-

In experiments 1 and 3 shaets were produced according to the invention by the thick and thin slurry method, respectively. The green sheets were suinclaved at 160°C.

By way of comparison sheets were produced in experiments 2 and 4 according to the known art, using unground fly sah instead of ground fly sah, while in experiment 6 sheets were produced according to the unground fly sah instead of ground fly sah being replaced by SiO<sub>2</sub> with an F-value higher than 1. The green sheets thin slurry method, the ground fly sah being replaced by SiO<sub>2</sub> with an F-value higher than 1. The green sheets were pressed and autoclaved as in experiments 1 and 3.

Compositions, calculated in percent by weight of solid material, and test results are shown in Table II.

Here and in the following "(C)" indicates that it is a comparative experiment.

It is evident that the sheets produced according to the invention exhibit highly improved strength proper-

ties and higher densities.

Furthermore, sheets were produced according to the invention, the green sheets being pressed not at
Furthermore, sheets were produced according to the invention, the green sheets being pressed not at
1.5 MPa, but at 10 MPa. These products exhibited densities between 1450 and 1600 kg/m² and MOR values
(wet) of about 35-37 MPa.

## Example 3

25

# Use of ground fly sah with different degrees of fineness.

Four series of experiments were carried out with production of sheets according to the Production Procedure by the thin stury method.

in experiments 6, 7 and 8 the ground fly ash 100, 300 and 500, respectively, was used. In experiment 9, which is a comparative experiment, the ground fly ash was replaced by unground fly ash. The working experiment was as in example 2.

procedure was as in example 2.

Compositions, calculated in percent by weight of solid material, and test results are shown in Table III.

It is evident that the strength properties of the products increase with increasing fineness of the ground fly ash.

# s Example 4

# Comperison between the MOR of wet and dry sheets.

Four series of experiments were performed with production of sheets according to the thin slurry method as described in example 2.

Compositions, calculated in percent by weight of solid material, and test results are shown in Table IV.

It is evident that there is only a very little difference between the MOR values for wet and dry products.

For autodiaved products belonging to the known art the ratio between the wet and dry strength typically lies within the range 0.55-0.75.

## Example 5

Comparison between sheets prepared according to the invention and sheets prepared according to the known art (thick stury, ordinary and accelerated curing).

Two times six series of experiments were performed with production of sheets according to the thick slurry version of the Production Procedure. The green sheets were divided into two batches and cured according to Procedure 2 and 3, respectively.

In experiments 14, 16 and 18 the ground fly ash G was used. In experiments 15, 17 and 19, which are comparative experiments, the ground fly ash was replaced by unground fly ash.

Compositions, calculated in percent by weight of solid material, and test results are shown in Table V. It is evident that the sheets produced according to the invention exhibit highly improved alrength properties and higher densitios.

#### Example 6

Comparison between sheets prepared according to the invention and sheets prepared according to the known art (thin shury, ordinary and accelerated curing).

Two times six series of experiments were performed with production of sheets according to the thin siumy version of the Production Procedure. The green sheets were divided into two batches and cured according to Procedure 2 and 3, respectively.

In experiments 20, 22 and 24 the ground fly ash G was used. In experiments 21, 23 and 26, which are comparative experiments, the ground fly ash was replaced by unground fly ash.

Compositions, calculated in percent by weight of solid material, and test results are shown in Table VI.

It is evident that the sheets produced according to the invention exhibit highly improved strength properties and higher densities.

#### 15 Industrial experiments.

#### Example 7.

20

Experiment on a full scale Hatschek machine.

# Expertment H1.

400 kg Sandame K (Incl. 10% water) were pulped for 15 min. with 9925 I water in a 10 m<sup>3</sup> Black Clawson pulper. The resulting pulp was refined to a degree of freeness of about 20° SR and transferred to a stock chest. Thereafter 10834 I pulp was pumped to a 26 m<sup>3</sup> Escher Wyss pulper and pulped for 15 min. with 10826 I water and 1250 kg EO (Incl. 10% water). Thereafter 3400 I silica-mix (52 weight-% ultra fine silica dust, 48 weight-% water) were added and mixed for 3 minutes. The resulting pulp had a solid material content of 14.88 weight-%.

280 kg of this pulp were mixed with 68 kg LSC cement and 25 kg ground fly eah G and water in order to obtain a suitable water to solid material ratio.

The resulting sturry was in known manner processed into flat sheets on a Hatschek machine.

The flat sheets were subsequently processed into confugated sheets in a conventional confugation machine, parily producing confugated sheets having a pitch of 177 mm and a height (i.e., distance from upper part of wave creat) of 51 mm (sheet thickness 6 mm), partly confugated sheets having a pitch of 130 mm and a height of 30 mm (sheet thickness 6 mm).

The corrugated effects were cured in a curing channel at 80°C for about 8 hours and subsequently autoclaved at 180°C for 10 hours, preceded by a pressurizing period of about 2 hours and subceeded by a depressurizing period of about 2 hours. The green sheets exhibited exceptional plastic properties, as there was no evidence of formation of cracks or wrinkles or other deformations after the corrugation.

#### Experiment H2

For comparison analogous cheets were prepared using the same working procedure as in experiment H1, the 25 kg ground fly ash G, however, being replaced by 25 kg unground fly ash.

#### Experiment H3

In this experiment sheats were prepared according to the invention using the same working procedure as in experiment H1, however, with the exclusive use of Stora 32, which was refined to 40° SR.

Test coupons were cut from the sheets produced in Experiment H1, H2 and H3 with the pitch 177 mm, and BT-max wet values were measured on the test coupons with rupture perpendicular to the corrugations.

The results are shown in Table VII.

It is evident that the products produced in experiment H1 exhibit superior strength properties in relation to the properties of the products produced in experiment H2, and that the products produced by the process according to the invention (H1 and H3) both have a remarkably high strength level.

### Example 8

Æ

# Experiments on a full scale Magnani Machine

An aqueous sturry having a weight of 1222 g par I (corresponding to a water/solid ratio about 3) and containing 3 parts by weight Sandarne K, 22° SR, 9 parts by weight EO, 8 parts by weight silica dust, 30 parts by weight ground fly ash G, and 50 parts by weight LSC cement was prepared as described in Example 7.

The siurry was dewatered to corrugated sheets on a Magnani Machine (pitch : 172 mm, height : 48 mm, thickness: 8-8 mm). The impressed sheets were precured and suinclaved as described in Example 7.

The products were tested by measuring density and MOR wat (waterscaked boards) in the machine direction:

Density 1100-1200 kg/m², MOR wet: 8.6 MPa.

It is evident that the present method is also usable in connection with the production of autoclaved sheets on a Magnani Machine.

## Claims

1. A process for the manufacture of asbestos-free fibre-reinforced shaped articles having a density of at least 1000 kg/m² with a matrix of a cured inorganic binder, in which green shaped articles are formed by dewatering an aqueous elurry of fibres and a matrix forming material comprising particles of an inorganic hydraulic binder, a particulate inorganic additive and possibly other additives containing an excess of water in relation to the amount necessary to secure curing of the hydraulic binder, and containing, on a dry weight basis, 3-20%, preferably 5-20%, in particular 7-15%, cellulose fibres, after which the green shaped articles are cured, characterized in that the matrix forming material comprises, on a dry weight basis,

40-90%, preferably 45-85%, of a coarse material with an average particle size of 35-12 μm, preferably 25-18 μm, preferably with a particle size distribution exhibiting only one maximum, comprising the hydrautic binder and possibly a silica- or efficate-containing, preferably pozzolanic active additive,

5-45%, preferably 10-40%, in particular 10-35%, of a fine inorganic, preferably silica- or silicate-containing, in particular pozzolanic active additive with an average particle size of 10-1 µm, preferably 7-3 µm, preferably with a particle size distribution exhibiting only one maximum.

3-25% of an ultra fine preferably pozzolanic active additive with an average particle size within the range 1-0.02  $\mu$ m, preferably less than 0.5  $\mu$ m, and

0-30% other additives.
2. A process eccording to claim 1 wherein the dewatering step is carried out on a Hatschek Machine and the green shaped articles are cured by autoclaving, characterized in that the matrix forming material comprises, on a dry weight basis,

40-75%, preferably 40-55%, in particular 45-50%, of the coarse material, 10-45%, preferably 15-40%, in particular 20-30%, of the fine additive,

3-25%, preferably 10-25%, in particular 14-22%, of the ultra fine additive, and 0-30% other additives.

- 3. A process according to claim 1 wherein the dewatering step is carried out on a Magnani Machine and the green shaped articles are cured by autoclaving, characterized in that the matrix forming material comprises, on a dry weight basis,
- 40-75%, preferably 40-60%, in particular 45-55%, of the coarse material.
- 10-45%, preferably 15-40%, in particular 25-35%, of the fine additive, 3-25%, preferably 3-20%, in particular 5-15%, of the ultra fine additive, and
- 0-30% other additives.
- 4. A process according to claim 1 wherein the dewatering step is carried out on a Hatschek Machine or a Magnani Machine and the green shaped articles are cured at atmospheric pressure, characterized in that the matrix forming material comprises, on a dry weight basis,
- 50-90%, preferably 60-90%, in particular 65-85%, of the coarse material,
- 5-35%, preferably 10-30%, in particular 10-20%, of the fine additive,
- 3-25%, preferably 6-20%, in particular 5-15%, of the ultra fine additive, and 0-30% other additives.
  - 6. A process according to any of the preceeding claims, characterized in that the 50-1-µm-fraction of the coarse material constitutes at least 80% by weight of said material, and that the weight ratio of the 50-10-µm-fraction to the 10-1-µm-fraction of this material is larger than 1.0, preferably larger than 1.2.
  - 8. A process according to any of the preceeding claims, characterized in that the 50-1-um-fraction of the fine additive constitutes at least 80% by weight of said material, and that the weight ratio of the 50-10-um-fraction to the 10-1-um-fraction of this material is less than 1.0, preferably less than 0.8.
  - 7. A process according to any of the preceeding claims, characterized in that at least 80% by weight of the ultra fine additive has a particle size within the range 0.6-0.02 µm.
- 8. A process according to any of the preceding claims, characterized in that the coarse material is Portland cement, preferably coarsely ground Portland cement having a Bialne-value less than 2500 cm²/g.
- 9. A process according to any of the preceding claims, characterized in that the coarse material comprises a mbdure of Portland cament and allica- or ellicate-containing, preferably pozzolanic active additive with a weight ratio Portland cament/additive larger than 1, preferably larger than 1.2.
- 10. A process according to claim 9, characterized in that the silica- or silicate-containing additive in the coarse fraction is unground fly eah end/or possibly ground quartz.
- 11. A process according to any of the preceding claims, characterized in that the additive in the fine additive is ground fly ash, possibly ground, possibly calcined moler, ground quartz, kleselgur, rice husk ash, calciumcarbonate or Wollastonite.
- 12. A process according to any of the preceding claims, characterized in that the ultra fine material is fine allica-containing filter dust from electrothermal production of allicon or ferrosilicon with a specific surface area of 5-200 m²/g, preferably about 25 m²/g, and an average particle diameter of about 0.1 µm.

### Revendications

- 1. Procédé de fabrication d'articles façonnés renforcés par des fibres, sans amiante, syant une masse volumique d'au moins 1000 kg/m³, comprenent une matrice d'un liant minéral durci, dans lequel des articles façonnés à l'état vert sont formés par déshydratation d'une suspension equeuse de fibres et d'une matière formant la matrice, comprenant des particules d'un liant hydraulique minéral, un additif minéral en particules, et facultativement d'autres additifs, contenant un excès d'eau par rapport è la quantité nécessaire pour assurer le durcissement du liant hydraulique, et contenant, sur base pondérale sèche, 3 à 20%, de préférence 5 à 20%, en particulier 7 à 15%, de fibres de celluloss, sprès quoi les articles façonnés à l'état vert sont durcis, caractérisé en ce que la matière formant la matrice comprend, sur base pondérale sèche,
- 40 à 90%, de préférence 45 à 85%, d'une matière grossière ayant une dimension granulométrique moyenne de 35 à 12 µm, de préférence 25 à 18 µm, avec de préférence une distribution granulométrique ne présentant qu'un seul maximum, comprenant le liant hydraulique et éventuellement un additif actif contenant de la ellice ou un allicate, de préférence pouzzoianique,
- 5 à 45%, de préférence 10 à 40%, en particulier 10 à 35%, d'un additif actif minéral fin contenant de préférence de la silice ou un silicate, en particulier pouzzoianique, ayant une dimension granulométrique moyenne de 10 à 1 μm, de préférence 7 à 3 μm, avec de préférence une distribution granulométrique ne présentant qu'un seul maximum.
  - 3 à 25% d'un additif actif ultrafin, de préférence pouzzolanique, ayant une dimension granulométrique

moyenne comprise dans l'intervalle de 1 à 0,02 μm, de préférence inférieure à 0,5 μm, et O à 30% d'autres additifs.

- 2. Procédé selon la revendication 1, dans lequel l'étape de déshydratation est exécutée sur une machine Hatschek et les articles asponnés à l'état vert sont durcis par autoclavage, caractèrisé en ce que la matière formant la matrice comprend, sur base pondérale sèche,
- 40 à 75%0, de préférence 40 à 55%, en particulier
- 45 à 50% de la matère grossière,
- 10 à 45%, de préférence 15 à 40%, en particuller
- 20 à 30%, de l'additif fin,
- 3 à 25%, de préférence 10 à 25%, en particuller 14 à 22%, de l'additif ultrafin, et
  - Q à 30% d'autres addilles.
  - 3. Procédé selon la revendication 1. dans lequel l'étape de déshydratation est exécutée sur une machino Magnani et les articles façonnés à l'état vert sont durcis par autoclavage, caractérisé en ce que la matière formant la matrice comprend, sur base pondérale sèche,
- 40 à 75%, de préférence 40 à 60%, en particulier
  - 45 à 55% de la matière grossière,
  - 10 à 45%, de préférence 15 à 40%, en particulier
  - 20 à 356%, de l'addiff fin,
  - 3 à 25%, de préférence 3 à 20%, en particulier 5 à 18%, de l'additf ultrafin, et
- 0 à 30% d'autres additifs.
  - 4. Procédé seion la revendication 1, dans lequel l'étape de déshydratation est exécutée sur une machine Hatachak ou une machine Magnani et les articles façonnée verts sont durcis à la pression abnosphérique, carectérisé en ce que la matière formant la matrice comprend, sur base pondérale sèche, 50 à 90%, de préférence 60 à 90%, en particulier
- 65 à 85% de la matière grossière,
- 5 à 35%, de préférence 10 à 30%, en particulier
- 10 à 20%, de l'additif fin.
- 3 à 25%, de préférence 5 à 20%, en particulier
- 5 à 15%, de l'additifutitalin, et
- 0 à 30% d'autres additifs.
  - 5. Procédé selon l'une quelconque des revendications précédentes, caractérisé en ce que la fraction de 50 à 1 µm de la matière grossière constitue au moins 80% en poide de ladite matière et en ce que te rapport en poide de la fraction 50 à 10 µm à la fraction de 10 à 1 µm de cette matière est supérieur à 1,0, de préférence supérieur à 1,2.
  - 6. Procédé selon l'une quelconque des revendications précédentes, caractérisé en ce que la fraction de 50 à 1 µm de l'additif fin constitue au moins 80% en poids de ladite matière et en ce que le rapport en poids de la fraction de 50 à 10 μm à la fraction de 10 à 1 μm de cette matière est inférieur à 1,0, de préférence Inférieur à 0,8.
  - Procédé selon l'une qualconque des revendications précédentes, caractérisé en ce qu'au moins 60% en poids de l'additif ultrafin a une dimension particulaire s'inscrivant dans l'intervalle de 0.5 à  $0.02~\mu m$
  - 8. Procédé selon l'une quelconque des revendications précédentes, caractérisé en ce que la matière grossière est du climent Portland, de préférence du climent Portland grossièrement broyé, ayant une surface spécifique solon Blaine Inférieure à 2500 cm²/g.
- 9. Procédé solon l'une quelconque des revendications précédentes, caractérisé en ce que la matière grossière comprend un mélange de ciment Portland et d'un additif actif contenant de la silice ou un silicate, de préférence pouzzoianique, le rapport en poids du ciment Portiand à l'additif étant supérieur à 1, de préférence supérieur à 1,2.
  - 10. Procédé seton la revendication 9, caractérisé en ce que l'additif contenant de la silice ou un silicate contenu dans la fraction grossière est de la cendre volante non broyée et/ou éventuellement du quartz broyé.
  - Procédé selon l'una qualconque des revendications précédentes, caractérisé en ce que l'additif de l'additif fin, est de la cendre volante broyée, du moler facultativement broyé et facultativement calciné, du quartz broyé, du kleselguhr, de la cendre de balles de riz, du carbonate de calcium ou de la wollestonite.
- 12. Procédé selon l'une quelconque des revendications précédentes, caractérisé en ce que la matière ultrafine est une poussière fine de filtres contenant de la silice, provenant de la production électrothermique de allichim ou de ferrosilicium et ayant une surface spécifique de 5 à 200 m²/g, de préférence d'environ 25 m<sup>2</sup>/g, et un diamètre moyen de particules d'environ 0,1 μm.

#### Ansprüche

1. Verfahren zur Herstellung von aabestfreien, faserverstärkten, geformten Artikein einer Dichte von mindestens 1000 kg/m² mit einer Matrix eines ausgehärtsten, anorganischen Binders, wobei frisch geformte Artikel gebildet werden, durch Entwässerung einer wäßrigen Aufschlämmung von Fasem und eines matrixbildenden Materials, umfassend Tellchen eines anorganischen, hydraulischen Binders, einen aus Tellchen bestehenden anorganischen Zusatz und möglicherweise andere Zusätze, die einen Wassenüberschuß im Vergleich zu der Menge enthalten, die erforderlich ist die Aushärtung des hydraulischen Binders sicherzustallen, und auf einer Trockengewichtsbasis 3-20%, vorzugsweise 5-20%, insbesondere 7-15% Zelluicsefasem enthaltend, wonach die frisch geformten Artikel ausgehärtet werden, dadurch gekennzeichnet, daß das matrobildende Material auf einer Trockangewichtsbasis,

40-90%, vorzugsweise 45-85%, eines groben Materials mit einer durchschnittlichen Teilchengröße von 35-12 μm, vorzugaweise 25-18 μm, vorzugaweise mit einer nur ein Maximum zelgenden Teilchengrößenvertellung, das den hydraulischen Binder und möglicherweise einen Silikeoder Silkat-enthaltenden,

vorzugsweise Puzzolan-aktiven Zusatz enthält,

5-45%, vorzugsweise 10-40%, insbesondere 10-35%, eines feinen anorganischen, vorzugsweise Silikaoder Silikat-enthaltenden, insbesondere Puzzolan-aktiven Zusatzes mit einer durchschnittlichen Tellichengröße von 10-1 µm, vorzugsweise 7-3 µm, vorzugsweise mit einer nur ein Meximum zeigenden Teilchengrößenvertellung.

3-25% eines uitrafeinen, vorzugsweise Puzzolan-aktiven Zusatzes mit einer durchschnittlichen Teilchengraße innerhalb des Bereichs 1-0,02 µm, vorzugsweise kleiner als 0,5 µm, und

0-30% andere Zusätze, umfaßt.

2. Verfahren nach Anspruch 1, worin der Entwässerungsschritt auf einer Hatschak-Maschine ausgeführt wird, und die frisch geformten Artikel durch Behandlung im Autoklaven ausgehärtet werden, dadurch gekennzeichnet, daß das matrixbildende Material auf einer Trockengewichtsbasis, 40-76%, vorzugsweise 40-55%, insbesondere 45-50%, das groben Materials. 10-45%, vorzugsweise 15-40%, insbesondere 20-30%, des feinen Zusaizes, 3-25%, vorzugaweise 10-25%, insbesondere 14-22%, des ultrafeinen Zusatzes, und

0-30% andere Zusätze, umfaßt.

3. Verfahren nach Anspruch 1, worin der Entwässerungsschritt auf einer Magnanl-Maschine ausgeführt wird und die frisch geformten Artikel durch Behandlung im Autoklaven ausgehärtet werden, dadurch gekennzelchnet, daß das matrixbildende Material euf einer Trockengewichtabasis, 40-75%, vorzugswelse 40-60%, Inabesondere 45-55%, des groben Materials, 10-45%, verzugsweise 15-40%, insbesondere 25-35%, des feinen Zusates, 3-25%, vorzugsweise 3-20%, insbesondere 5-15%, des uitrafeinen Zusatzes, und

0-30% andere Zusätze, umfaßt.

4. Verfahren mach Anspruch 1, worin der Entwässerungsschritt auf einer Hatschek-Maschine oder einer MagnaniMaschine ausgeführt wird und die frisch geformten Artikel bei Luftdruck ausgehärtet werden, dadurch gekennzeichnet, daß das matrotbildende Material auf einer Trockengewichtsbasis,

50-90%, varzugaweise 60-90%, insbesondere 65-85%, des groben Materials, 5-35%, vorzugsweise 10-30%, insbesondere 10-20%, des feinen Zusstzes, 3-25%, vorzugsweise 5-20%, insbesondere 5-15%, das ultrafeinen Zusatzes, und 0-30% endere Zusätze, umfaßt.

5. Verfahren nach einem der vorhergehenden Ansprüche, dadurch gekennzelchnet, daß der 50-1 µm-Bruchteil des groben Materials mindestens 80 Gew.-% dieses Materials ausmacht, und daß das Gewichtsverhältnis des 50-10 µmBruchteils zum 10-l µm-Bruchteil dieses Materials größer als I,0, vorzugswelse größer sie 1,2 ist.

6. Verfahren nach einem der vorhergehenden Ansprüche, da-, durch gekennzeichnet, daß der 50-i µm-Bruchteil des feinen Zusatzes mindestens 80 Gaw.-% dieses Materials ausmacht, und daß das Gewichtsverhältnie des 50-10 µmBruchtells zum 10-1 µm-Bruchtell dieses Materials kleiner als I,0, vorzugsweise kleiner als 0,8 lst.

7. Verfahren nach einem der vorhergehanden Ansprüche, dadurch gekannzeichnet, daß mindestens 80 Gew.-% des uitrafeinen Zusatzes eine Tellchengröße innerhalb des Bereiche 0,5-0,02 µm aufwelst.

8. Verfahren nach einem der vorhergehenden Ansprüche, dadurch gekannzeichnet, daß das grobe Material PortlandZement, vorzugsweise grob gemahlener Portland-Zement mit einem Blaine-Wert kleiner

9. Verfahren nach einem der vorhergehenden Ansprüche, dadurch gekannzeichnet, daß das grobe Material eine Mischung aus Portiand-Zement und einem Silika- oder Silikat- enthaltenden, vorzugsweise

Puzzolan-aktiven Zusatz umfaßt, mit einem Gawichtsverhältnis Portland-Zement/Zusatz, das größer als 1, vorzugaweise größer als 1,2 ist

- 10. Verfahren nach Anspruch 9, dadurch gakennzeichnet, daß der Silika- oder Silikat-enthaltende Zusatz in dem groben Bruchteil ungermahlene Flugasche und/oder möglicherweise gemahlener Quartz ist.
- 11. Verfahren nach einem der vorhergehenden Anaprüche, dedurch gekennzeichnet, daß der Zusatz in dem feinen Bruchteil gemahlene Flugasche, möglicherweise gemahlener, möglicherweise geglühter Moler (Diatomeanarde), gemahlener Quartz, Kleselgur, Reiskielanasche, Calchumcarbonat oder Wollastonit let.
- 12. Verfahren nach einem dar vorhargehanden Ansprüche, dadurch gekennzeichnet, daß das uitrafeine Material feiner Silica-entheitender Fiterstaub aus der elektrothermischen Silicium- oder Ferrosilicium-harstellung ist, mit einem Bereich der spezifischen Oberfläche von 5-200 m²/g, vorzugsweise um 25 m²/g, und einem durchschnittlichen Teilchendurchmesser von ungefähr 0,1 µm.
